# Correlation-bound states of $\mathrm{C}_{60}^{-}$anion 

E. V. Gromov*, S. Klaiman, and L. S. Cederbaum<br>Theoretical Chemistry, University of Heidelberg, Germany<br>*evgeniy.gromov@pci.uni-heidelberg.de

We report on large-scale ab initio electronic structure calculations for the bound electronic states of the $\mathrm{C}_{60}^{-}$anion. $\mathrm{C}_{60}$ (buckminsterfullerene) is known to be a strong electron acceptor, able to capture one or several electrons [1]. Among the $\mathrm{C}_{60}^{-}$species it is only the ground state ${ }^{2} \mathrm{~T}_{1 \mathrm{u}}$ that has been thoroughly studied from both experimental and theoretical point of view [2]. It is however very little known to date about other, less bound (excited) states of $\mathrm{C}_{60}^{-}$. Are there such states at all and how many are there? In fact, identifying such states in $\mathrm{C}_{60}^{-}$represents a big challenge. The main obstacles here are the large number of electrons ( 241 valence electrons) and, what is more crucial, the necessity of a proper treatment of electron correlation effects. These effects turn out to be strong already in neutral $\mathrm{C}_{60}$ and "go off scale" in the $\mathrm{C}_{60}^{-}$anion. It is in fact the electron correlation (disperse-type) effects that were found to bind the extra electron in the $\mathrm{C}_{60}^{-*}$ anion excited states. These states are therefore termed correlation-bound states.

Using the highly accurate coupled cluster (EOM-EA) method we demonstrate that $\mathrm{C}_{60}^{-}$possesses at least three correlation-bound, excited electronic states. These are ${ }^{2} \mathrm{~T}_{1 \mathrm{~g}},{ }^{2} \mathrm{~T}_{2 \mathrm{u}}$ and ${ }^{2} \mathrm{~A}_{\mathrm{g}}$ in order of decreasing the electron binding energy (see the figure below). Here it is noteworthy that ${ }^{2} \mathrm{~A}_{\mathrm{g}}$ was only very recently predicted to exist (being bound) [3] whereas the ${ }^{2} \mathrm{~T}_{2 \mathrm{u}}$ state has been unknown to date. In the present work we focus on characterization of the above states in terms of their binding energies as well as with regard to their electronic structure, in particular the spatial distribution of the extra electron. To this end we employ the natural bond occupation analysis based on the computed one-electron densities.
